

TTM AS-level Traceroutes

Matching IPs to ASes

René Wilhelm

New Projects Group
RIPE NCC
<wilhelm@ripe.net>

Motivation

- TTM performs frequent traceroutes to find closest IP route for delay measurements
 - Many small changes in routes, due to load balancing and rerouting inside provider networks
 - minimal changes in delays
 - Want a handle on bigger changes in routing, when different upstream or backbone provider is used
- transform collected IP traces to AS level traces

Traceroute from TBx to TBy

8 Hops recorded in the traceroute

4 Autonomous systems traversed

Matching IPs to ASnums

- Internet Routing Registry
 - Autonomous systems register the prefixes they originate
 - find best match
- Global Routing table
 - prefixes and aspaths, last as in path is seen as originator
 - find best match
- Currently, TTM uses IRR
 - speed, matching done offline, traceroutes on boxes simple
 - general feeling IRR not up to date; check and quantify

Internet Routing Registry

- No single authoritative registry:

The screenshot shows the IRR website interface. At the top left is the IRR logo with the text "INTERNET ROUTING REGISTRY". To the right, the title "List of Routing Registries" is displayed in red, with the URL <http://www.irr.net/docs/list.html> next to it. Below the title are navigation links: "OverView", "RPSL", "FAQ", and "Home". The main content area is titled "List of Routing Registries" and contains a grid of 40 links, each preceded by a bullet point. The links are arranged in four columns and ten rows.

Internet Routing Registry (2)

- Not practical to query everyone of them
 - time consuming, remote locations, slow connections
- Compromise:
 - whois.ripe.net mirrors RADB, APNIC, ARIN, CW, VERIO
 - local to TTM analysis machine, fast response
 - retrieve all route objects matching the IP
 - find longest prefix match, return AS number of the object
- May return more than 1 AS number
 - route registered in multiple registries with different AS
 - route registered more than once in same registry

Global Routing Table

- Not one single global routing table
 - aggregation and filtering lead to different views at different locations
- RIPE NCC 's RIS project
 - collects BGP updates at 10 locations, from 302 peers
 - daily dumps of Routing Table stored in per collector databases
 - accessible from one central machine

RIS Routing Tables

- Join data from all RIS collectors in one table
 - prefix + origin AS
 - 132995 prefixes (july 29th)
- Map IP to longest matching prefix
- Can return more than 1 AS number
 - multiple origin AS in one route collector
 - different origin AS in different route collectors (e.g. due to aggregation)

Results for TTM

- Typical day in the life of TTM
 - 63 active boxes, 6 traces per hour to each other box
 - 13,322,691 IP addresses, but many duplicates
 - 3618 unique IP addresses to match with AS
- IRR: 2856 IPs in 251 prefixes (79%) matched
- RIS: 3584 IPs in 297 prefixes (99%) matched
- RIS does a better job, but look at the differences

IRR vs. RIS

- 51 prefixes **not found** by IRR are in RIS
 - 4 of these have multiple origin AS in RIS
check ARIN,RIPE,APNIC database → exchange points
 - 80% of missing entries are with 5 large ISPs
- 17 prefixes have **different** AS in RIS and IRR
 - objects not updated after mergers, prefixes once announced by 2 or more ASes, now by single AS
 - objects not maintained, outdated
- 11 prefixes represented by **aggregates**
 - either RIS or IRR has a more specific, with different AS

IRR vs RIS (2)

- 5 prefixes not found by RIS **are** in Routing Registry
 - exchange points
- 9 prefixes **multiple objects** in IRR, more than 1 AS
 - only 1 AS in RIS → outdated objects?
- 17 IPs (from 7 /24s) **not** found in RIS **nor** in IRR
 - RFC1918 addresses
 - exchange points
 - internal infrastructure

RIS vs. IRR matches: summary

- For TTM traceroutes IRR is ~80% correct
- Value of IRR would increase If large ISPs would register and maintain route objects
- Currently, routing tables are the best approach.
 - RIS route collectors provide a publicly available view from different vantage points (US, Europe, Japan) with 302 total peers

TTM AS traces vs. BGP aspath

- Two clear differences
 - exchange points
 - traceroute detects IP of interface on exchange, if a match is found it maps to the exchange AS, not the peer AS
e.g. from RIPE NCC: 3333 1200 1103 ...
 - unknown AS in the traceroute aspath
 - 1 or more consecutive IP hops not matched or not responding
 - can't tell if they belong to preceding AS, next AS or a different AS altogether; flag it with AS number 0.
- In depth comparison planned
 - for sites which both host a testbox and peer with RIS

Conclusions & Future

- RIS provides a good means to match IP to AS
- IRR could use better commitment by ISPs
- TTM will switch to using RIS for IP-AS mapping in the traceroute database
- Expand code to also handle IPv6
- RIPE-NCC will set up an IP-AS mapping service
 - Derived product: traceroute -A with AS from RIS
